AOSC 621 Lesson 5-6

Absorption Line Intensity and Levels for Vibrational, Rotational and Electronic Absorption
Absorption in molecular lines and bands

- Molecules have three types of energy levels - electronic, vibrational, and rotational
- Transitions between electronic levels occur mainly in the ultraviolet
- Transitions between vibrational levels - visible/near IR
- Transitions between rotational levels - far IR/mm wave region
- \( \text{O}_2 \) and \( \text{N}_2 \) have essentially no absorption in the IR
- 4 most important IR absorbers \( \text{H}_2\text{O}, \text{CO}_2, \text{O}_3, \text{CH}_4 \)
The microwave absorption spectrum of CO
Absorption by gaseous species

- Particles in the atmosphere are absorbers of radiation.
- Absorption is inherently a quantum process.
- A transition takes place from an initial quantum state to a higher quantum state.
- When the photon energy is close to the energy difference between the lower and the higher states, the process is called resonance. And the absorption is high.
- When the opposite is true the absorption is small.
Generally **vibrational transitions** occur in conjunction with **rotational transitions**. Consequently, it is possible to observe both rotational and **vibrational transitions** in the vibrational spectrum.

The energy of rotational transitions is on the order of $10^{-23}$ J whereas vibrational transitions have energies on the order of $10^{-20}$ J. Therefore, highly-resolved vibrational spectra will contain **fine structure** corresponding to the rotational transitions that occur at the same time as a vibrational transition.

Rotational-vibrational spectra will also show some fine structure due to the presence of different **isotopes** in the spectrum.
Hierarchy of energy levels

Total excitation energy of molecules:

\[ E_{\text{tot}} = E_{\text{el}} + E_{\text{vib}} + E_{\text{rot}} \]
Absorption by gaseous species

• This energy selectivity is an outstanding characteristic of absorption. Scattering is generally much less selective and occurs over a much larger region of the spectrum.

• As we shall see later, molecules have a myriad of discrete energy levels and hence have complex absorption spectra.

• One reason for our interest in the spectra of molecules lies in the fact that many molecules have absorption features in the thermal infra-red and these are responsible for the thermal equilibrium of the atmosphere.

• Another is that many molecules absorb strongly on the ultraviolet, where the photons have enough energy to break apart the molecules. The resulting radicals start the chemical processes in both the troposphere and stratosphere.
Normal modes of vibration

For linear: $3N-5$ modes

In general: $3N-6$ modes
Various forms of molecular vibration
Selection Rules

• Not all vibration excitation in molecules produces radiation.
• To produce radiation one needs to have an oscillating dipole. When the molecule is set into a vibration mode, the combined electric field at the center of mass must also oscillate.
• \( \text{O}_2 \text{ and } \text{N}_2 \), homonuclear molecules, do not possess an oscillating dipole at their center of mass when in the ground state and so do not show vibrational spectra in the IR.
Rotational levels

- Consider a diatomic molecule with different atoms of mass $m_1$ and $m_2$, whose distance from the center of mass are $r_1$ and $r_2$ respectively.

![Diagram of a diatomic molecule with moment of inertia formula]

- The moment of inertia of the system about the center of mass is:

$$I = m_1 r_1^2 + m_2 r_2^2$$
H₂O

- Most important IR absorber
- Asymmetric top → Nonlinear, triatomic molecule has complex line structure, no simple pattern
- 3 different moments of inertia ($I_A, I_B, I_C$)
- 3 Vibrational fundamental modes

![H₂O molecule diagram]

- Symmetric stretch $\lambda_1 = 2.74 \mu$m
- Bend $\lambda_2 = 6.25 \mu$m
- Asymmetric stretch $v_3 = 2.66 \mu$m

- Higher order vibrational transitions ($\Delta \nu > 1$) give weak absorption bands at shorter wavelengths in the shortwave bands
- $^2$H isotope (0.03% in atm) and $^{18}$O (0.2%) adds new (weak) lines to vibrational spectrum
- Overtones and combinations of rotational and vibrational transitions lead to several more weak absorption bands in the NIR
Absorption Spectrum of H$_2$O

$\lambda_1 = 2.74 \, \mu m$

$\lambda_2 = 6.25 \, \mu m$

$\lambda_3 = 2.66 \, \mu m$
CO$_2$

- Linear $\rightarrow$ no permanent dipole moment, no pure rotational spectrum
- Fundamental modes:
  - Symmetric stretch $\lambda_1 = 7.5 \, \mu m \Rightarrow$ IR inactive
  - Asymmetric stretch $\lambda_2 = 15 \, \mu m$
  - Bend $\lambda_2$

- $\lambda_1$ vibration is a parallel band (dipole moment oscillates parallel to symmetric axis), transition $\otimes J = 0$ is forbidden, greater total intensity than $\lambda_2$ fundamental
- $\lambda_2$ vibration is perpendicular band
- $\lambda_3$ fundamental strongest vibrational band but $\lambda_2$ fundamental most effective due to “matching” of vibrational frequencies with terrestrial Planck emission functions
- $^{13}$C isotope (1% of C in atm) and $^{17/18}$O isotope (0.2%) cause a weak splitting of rotational and vibrational lines in the CO$_2$ spectrum
IR Absorption Spectrum of CO$_2$

$^a$ The cut-off for $S_0$ is $10^{-20}$ cm. Where bands have identical upper and lower states, they are resonating members of a Fermi triplet. Band intensities for upper state and isotopic bands are given in terms of the total number of molecules of all species and all levels.
Ozone is primarily present in the stratosphere aside from anthropogenic ozone pollution which exists in the troposphere.

Asymmetric top $\rightarrow$ similar absorption spectrum to H$_2$O due to similar configuration (nonlinear, triatomic).

Strong rotational spectrum of random spaced lines.

Fundamental vibrational modes:

- Symmetric stretch: $\lambda_1 = 9.1$ $\mu$m
- Bend: $\lambda_2 = 14.3$ $\mu$m
- Asymmetric stretch: $\lambda_3 = 9.6$ $\mu$m

- 14.3 $\mu$m band masked by CO$_2$ 15 $\mu$m band.
- Strong $\lambda_3$ band and moderately strong $\lambda_1$ band are close in frequency, often seen as one band at 9.6 $\mu$m.
- 9.6 $\mu$m band sits in middle of 8-12 $\mu$m H$_2$O window and near peak of terrestrial Planck function.
- Strong 4.7 $\mu$m band but near edge of Planck functions.
IR Absorption Spectrum of O$_3$

- $\lambda_1 = 9.1 \mu m$
- $\lambda_2 = 14.3 \mu m$
- $\lambda_3 = 9.6 \mu m$

*The ground states are all 0000. The intensities of isotope bands are based on the total number of molecules of all species. ¹³C atoms form 1.108% of the total carbon.*
**N₂O**

- Linear, asymmetric molecule (has permanent dipole moment)
- Has rotational spectrum and 3 fundamentals
- Absorption band at 7.8 μm broadens and strengthens methane’s 7.6 μm band.
- 4.5 μm band less significant because at edge of Planck function.

- Fundamental modes:

  - **Symmetric stretch** $\lambda_1 = 7.8$ μm
  - **Asymmetric stretch** $\lambda_3 = 4.5$ μm
  - **Bend** $\lambda_2 = 17.0$ μm
IR Absorption Spectrum of N$_2$O

$\lambda_1 = 7.8 \text{ µm}$

$\lambda_2 = 17 \text{ µm}$

$\lambda_3 = 4.5 \text{ µm}$
Total IR Absorption Spectrum of the Atmosphere
Vibrational levels

- Consider a diatomic molecule. The two atoms are bound together by a force, and can oscillate along the axis of the molecule.
- The force between the two atoms is given by
  \[ F = -kx = m \frac{d^2x}{dt^2} \]
- The solution of which is
  \[ x = x_0 \sin(2\pi \nu_0 t + \phi) \]
Vibrational levels

• $\nu_0$ is known as the vibrational frequency

$$\nu_0 = \frac{1}{2\pi} \sqrt{\frac{k}{m}}$$

• theoretically $\nu_0$ can assume all values

• However in quantum mechanics these values must be discrete

$$E_\nu = h\nu_0(\nu + 1/2)$$

• $\nu$ is the vibrational quantum number
Rotational levels

- The classical expression for energy of rotation is

\[ E_r = \frac{I \omega^2}{2} = \frac{L^2}{2I} \text{ where } L= \text{angular momentum} \]

\[ L^2 \rightarrow \left( \frac{h}{2\pi} \right)^2 J(J+1) \]

- where \( J \) is the rotational quantum number

\[ E(J) = \frac{1}{2I} \left( \frac{h}{2\pi} \right)^2 J(J+1) = h c B_v J(J+1) \]

\[ B_v = \frac{h}{8\pi^2 c I} \text{ the rotational constant} \]
Vibrating Rotator

- If there were no interaction between the rotation and vibration, then the total energy of a quantum state would be the sum of the two energies. But there is, and we get

\[
\frac{E(v, J)}{hc} = \omega_0 (v + 1/2) - \omega_0 x_e (v + 1/2)^2 \\
+ B_{vJ} J(J + 1) + D_{vJ} J^2 (J + 1)^2
\]

- The wavenumber of a spectral line is given by the difference of the term values of the two states
Energy levels of a vibrating rotator

**Transition rules**

- Not all transitions are allowed - selection rules, e.g. in rotational transitions changes in J are restricted to 0, and ±1

- The complete set of rotational transitions between two vibrational levels is known as a ‘band’

- A band normally consists of three separate sequences; if ∆J=0 we have the Q branch, ∆J=1 the R branch, ∆J=-1 the P branch
Selection rules

*a The lower states are all 00'0. Only the 4.5 $\mu$m band contains significant isotopic lines. The cut-off for $S_e$ is $10^{-18}$ cm.
CO

- Linear diatomic, simple spectrum
- Vibration-rotation band at ~4.67 µm

Diagram showing the R branch, P branch, and no Q branch.
Line strengths

- The line strength is for an isolated line, $S$. In the case of a vibration-rotation band we define a band strength.

- To determine the line strength of an individual transition we need to determine the population of the lowest level for each vibration/rotation level. As the electronic levels have a large energy difference, nearly all molecules are in the so-called ‘ground’ state.
Line strengths

• The population of the vibrational levels is governed by the Boltzmann distribution

\[ N(\nu) = N_0 \exp \left( - \frac{G(\nu)}{k_B T} \right) \]

where \( N_0 \) is the total number of molecules per cm\(^3\)

• For each rotational number \( J \) there are \((2J+1)\) levels.

\[ N(J) = N_0 \frac{hcB_{\nu}}{k_B T} (2J + 1) \exp -\frac{E(J)}{k_B T} \]
Relative populations of rotational levels in HCl.
Electronic levels

- In molecules we have two opposing forces - the repelling force of the nuclei, and the binding force of the electrons.
- If the orbit of the electrons change then the binding force will change, i.e. the net potential energy of the molecule will change.
- This means that the inter-atomic distance will change.
- Different electronic levels will have different rotational and vibrational constants.
Potential energy diagram for a typical diatomic molecule

- The x axis is the inter-nuclear separation $r$, and the y axis is the potential energy.

- As the two atoms come together the electrons of each overlap and produce a binding force which stabilizes the molecule.

- Hence the ‘potential well’.

- The shaded area represents energies for which the molecule can be broken apart. When this occurs the molecule is not restricted to absorbing discrete energies as any additional energy can be taken away by the atoms as kinetic energy which is not quantized.

- The shaded area is referred to as a dissociation continuum.
Franck-Condon principle

• The time for a transition is extremely small, and in this time the atoms within a molecule can be assumed not to move.

• Franck and Condon therefore postulated that on a potential energy diagram the most likely transitions would be vertical transitions.
Franck-Condon principle
Photodissociation

- The fragmentation of a chemical species following the absorption of light is most important in atmospheric chemistry.
- Optical dissociation occurs from the electronic state to which absorption takes place.
- Absorption leading to dissociation gives rise to a continuum, as additional energy can be taken away by the fragments as kinetic energy, which is not quantized.
- The atomic products can be in an excited state.
Photodissociation

- Two main mechanisms are recognized for dissociation, optical dissociation and pre-dissociation. These processes will be illustrated in the $O_2$ molecule.

- Optical dissociation occurs within the electronic state to which the dissociation first occurs. The absorption spectrum leading to dissociation is a continuum.

- At some longer wavelength the spectrum shows vibrational bands. The bands get closer together as the limit is approached – the restoring force for the vibration gets weaker.
Discrete absorption in molecular oxygen, (Schumann-Runge bands)
Absorption continuum in molecular oxygen (Schumann-Runge continuum)
Recall that:

$$\alpha_n(\nu) = S \Phi(\nu)$$  absorption cross section

$$[m^2] = [m^2 s^{-1}] [Hz^{-1}]$$

$$\alpha_m(\nu) = S \Phi(\nu)$$  mass absorption coefficient

$$\int \Phi(\nu) d\nu = 1$$

$$[m^2 kg^{-1}] = [m^2 s^{-1} kg^{-1}] [Hz^{-1}]$$

and by definition:

Why do absorption have lines shapes that are not $\delta$-functions?

• Broadening due to Heisenberg’s Uncertainty Principle (natural broadening)
• Broadening due to collisions (pressure broadening)
• Broadening due to Doppler effects
Natural broadening

• The line width (full width at half maximum) of the Lorentz profile is the damping parameter, γ.

• For an isolated molecule the damping parameter can be interpreted as the inverse of the lifetime of the excited quantum state.

• If absorption line is dampened solely by the natural lifetime of the state this is natural broadening

\[ \Delta E \Delta t \approx \frac{\hbar}{2\pi}, \quad \Delta t \approx \frac{\hbar}{2\pi \cdot h \Delta \nu} \approx \frac{1}{2\pi \Delta \nu} \]

• This is consistent with the Heisenberg Uncertainty Principle
Heisenberg uncertainty principle

- Heisenberg uncertainty principle states that certain pairs of physical properties, such as position and momentum of an electron or any other particle, cannot be simultaneously known to arbitrarily high precision.

- That is, a system cannot be defined to have simultaneously singular values of these pairs of quantities. A minimum exists for the product of the uncertainties in these properties that is equal to or greater than one half of the reduced Planck constant ($\hat{h} = h/2\pi$).
Natural line width

Excited molecule decays spontaneously. Upper state has finite lifetime $t_R \equiv \Delta t$

Heizenberg’s Uncertainty Principle:

$$\Delta E \Delta t \approx \frac{h}{2\pi} \Rightarrow \Delta \nu \Delta t \approx \frac{1}{2\pi} \Rightarrow \Delta t \equiv t_R \approx \left(2\pi \Delta \nu\right)^{-1}, \text{ so } \Delta \nu \approx \frac{1}{2\pi t_R} \equiv \alpha_N \text{ (natural line width)}$$

Recall that:

Electronic transitions:

$$t_R \approx 10^{-8} \text{ s} \Rightarrow \alpha_N \approx 5 \times 10^{-4} \text{ cm}^{-1}$$

Vibrational transitions:

$$t_R \approx 0.1 \text{ s} \Rightarrow \alpha_N \approx 5 \times 10^{-11} \text{ cm}^{-1}$$

Rotational transitions:

$$t_R \approx 1-10 \text{ s} \Rightarrow \alpha_N \approx 10^{-12} \text{ cm}^{-1}$$
Pressure broadening

• For an isolated molecule the typical natural lifetime is about $10^{-8}$ s, $5 \times 10^{-4}$ cm$^{-1}$ line width

• However as the pressure increases the distance between molecules becomes shorter. We can view the outcome in two ways

• (1) Collisions between molecules can shorten the lifetime, and hence the line width becomes larger.

• (2) As the molecules get closer their potential fields overlap and this can change the ‘natural line width’.

• Because the molecules interact with each other, molecule collisions reduce the lifetime of the upper state, and thus broaden the line.
Pressure broadening

- Clearly the line width will depend on the number of collisions per second, i.e., on the number density of the molecules (Pressure) and the relative speed of the molecules (the square root of the temperature).

\[ \alpha_L \approx \alpha_L(\text{STP}) \frac{n v_{\text{rel}}}{n_L v_{\text{rel}}(\text{STP})} = \alpha_L(\text{STP}) \frac{n \sqrt{T}}{n_L \sqrt{T_0}} \]
Doppler broadening

- Second major source of line broadening
- Molecules are in motion when they absorb. This causes a change in the frequency of the incoming radiation as seen in the molecules frame of reference
- Let the velocity be $v$, and the incoming frequency be $\nu$, then

\[
\nu' = \nu + \frac{v \cos \theta}{\lambda} = \nu + \frac{v^2 \cos \theta}{c} = \nu \left(1 + \frac{v}{c} \cos \theta \right)
\]
Doppler broadening

- Line broadening due to the random motion of atmospheric molecules
- Doppler effect: The frequency of emitted light is higher if the emitter (molecule) approaches the detector, lower if it moves away from the detector.
- For a Maxwell-Boltzmann distribution of molecular velocities it can be shown that the line broadening due to the Doppler effect produces a Gaussian line shape:
  \[
  \Phi_D(v) = \frac{1}{\pi \alpha} \exp \left[ -\frac{(v - v_0)^2}{\alpha^2} \right]
  \]
  where the Doppler 1/e-(half) width (independent of pressure) is
  \[
  \alpha_D = \frac{v_0}{c} \frac{1}{D_0} = \frac{1}{2k_BT/m} \]
  Properly normalized and the line half-width at half
